Eval order: What is the output?

```c
#include <stdio.h>

int f1(void) { puts("f1"); return 2; }
int f2(void) { puts("f2"); return 3; }
int f3(void) { puts("f3"); return 5; }
int f4(void) { puts("f4"); return 7; }

int ff(int a, int b, int c) {
    puts("ff");
    return a + b + c;
}

int main() {
    printf("x=%d\n", ff(f1(), f2() * f3(), f4()));
}
```

f4  f2  f3  f1  ff  x=24
Memory layout of C programs

- stack
- heap
- uninitialized data (bss)
- initialized data
- code (text)

Command-line arguments and environment variables

low address

high address

initialized to zero by exec

read from program file by exec

From http://www.geeksforgeeks.org/memory-layout-of-c-program/
A code segment, also known as a text segment, is one of the sections of a program in an object file or in memory, which contains executable instructions.

As a memory region, a text segment may be placed below the heap or stack in order to prevent heaps and stack overflows from overwriting it.

Usually, the text segment is sharable so that only a single copy needs to be in memory for frequently executed programs, such as text editors, the C compiler, the shells, and so on. Also, the text segment is often read-only, to prevent a program from accidentally modifying its instructions.
Initialized data segment, usually called simply the Data Segment. A data segment is a portion of virtual address space of a program, which contains the global variables and static variables that are initialized by the programmer.

Note that, data segment is not read-only, since the values of the variables can be altered at run time.

This segment can be further classified into initialized read-only area and initialized read-write area.

For instance the global string defined by `char s[] = "hello world"` in C and a C statement like `int debug=1` outside the main (i.e. global) would be stored in initialized read-write area. And a global C statement like `const char* string = "hello world"` makes the string literal “hello world” to be stored in initialized read-only area and the character pointer variable string in initialized read-write area.

Ex: `static int i = 10` will be stored in data segment and `global int i = 10` will also be stored in data segment
Uninitialized data segment, often called the “bss” segment. Data in this segment is initialized by the kernel to arithmetic 0 before the program starts executing.

Uninitialized data starts at the end of the data segment and contains all global variables and static variables that are initialized to zero or do not have explicit initialization in source code.

For instance a variable declared `static int i;` would be contained in the BSS segment. For instance a global variable declared `int j;` would be contained in the BSS segment.
Stack

The stack area traditionally adjoined the heap area and grew the opposite direction; when the stack pointer met the heap pointer, free memory was exhausted. (With modern large address spaces and virtual memory techniques they may be placed almost anywhere, but they still typically grow opposite directions.)

The stack area contains the program stack, a LIFO structure, typically located in the higher parts of memory. On the standard PC x86 computer architecture it grows toward address zero; on some other architectures it grows the opposite direction. A “stack pointer” register tracks the top of the stack; it is adjusted each time a value is “pushed” onto the stack. The set of values pushed for one function call is termed a “stack frame”; A stack frame consists at minimum of a return address.

Stack, where automatic variables are stored, along with information that is saved each time a function is called. Each time a function is called, the address of where to return to and certain information about the caller’s environment, such as some of the machine registers, are saved on the stack. The newly called function then allocates room on the stack for its automatic and temporary variables. This is how recursive functions in C can work. Each time a recursive function calls itself, a new stack frame is used, so one set of variables doesn’t interfere with the variables from another instance of the function.
Heap

Heap is the segment where dynamic memory allocation usually takes place. The heap area begins at the end of the BSS segment and grows to larger addresses from there. The Heap area is managed by malloc(), realloc(), and free(), which may use the brk() and sbrk() system calls to adjust its size. (note that the use of brk/sbrk and a single “heap area” is not required to fulfill the contract of malloc/realloc/free; they may also be implemented using mmap to reserve potentially non-contiguous regions of virtual memory into the process’ virtual address space). The Heap area is shared by all shared libraries and dynamically loaded modules in a process.
The `size(1)` command reports the sizes (in bytes) of the text, data, and bss segments. (for more details please refer man page of size(1), objdump(1))

```c
#include <stdio.h>

int main(void)
{
    return 0;
}
```

```
$ gcc memory-layout.c -o memory-layout
$ size memory-layout
```

```
text  data  bss  dec  hex  filename
960  248  8  1216  4c0  memory-layout
```
added one global variable in program, now check the size of bss

#include <stdio.h>

int global; /* Uninitialized variable stored in bss*/

int main(void)
{
    return 0;
}

text       data        bss        dec        hex    filename
960        248        12          1220      4c4    memory-layout
Let us add one static variable which is also stored in bss.

```c
#include <stdio.h>

int global; /* Uninitialized variable stored in bss*/

int main(void)
{
    static int i; /* Uninitialized static variable stored in bss */
    return 0;
}
```

<table>
<thead>
<tr>
<th>text</th>
<th>data</th>
<th>bss</th>
<th>dec</th>
<th>hex</th>
<th>filename</th>
</tr>
</thead>
<tbody>
<tr>
<td>960</td>
<td>248</td>
<td>16</td>
<td>1224</td>
<td>4c8</td>
<td>memory-layout</td>
</tr>
</tbody>
</table>
Let us initialize the static variable which will then be stored in Data Segment (DS)

```c
#include <stdio.h>

int global; /* Uninitialized variable stored in bss*/

int main(void)
{
    static int i = 100; /* Initialized static variable stored in DS*/
    return 0;
}
```

<table>
<thead>
<tr>
<th>text</th>
<th>data</th>
<th>bss</th>
<th>dec</th>
<th>hex</th>
<th>filename</th>
</tr>
</thead>
<tbody>
<tr>
<td>960</td>
<td>252</td>
<td>12</td>
<td>1224</td>
<td>4c8</td>
<td>memory-layout</td>
</tr>
</tbody>
</table>
Let us initialize the global variable which will then be stored in Data Segment (DS)

```c
#include <stdio.h>

int global = 10; /* initialized global variable stored in DS*/

int main(void)
{
    static int i = 100; /* Initialized static variable stored in DS*/
    return 0;
}
```

<table>
<thead>
<tr>

Segmentation fault (core dumped)
Stack frame

return address (or you never come back)
ptr to previous frame (-fomit-frame-pointer)
arguments (first 6 in registers AMD64)
local variables

```c
void f()
{
    int a[1];
    printf("%p", &a[0]);
    printf("%d", a[-15]);
}
```

More details:
http://eli.thegreenplace.net/2011/09/06/stack-frame-layout-on-x86-64/
Memory allocation

```c
#include <stdlib.h>

void* malloc(size_t size);
void  free(void *ptr);
void* calloc(size_t nmem, size_t size);
void* realloc(void *ptr, size_t size);
```

Example:
```c
double* x = malloc(1000 * sizeof(*x))
double* x = calloc(1000, sizeof(*x))
double* x = realloc(x, 10000 * sizeof(*x))
free(x)
```

Note: size_t is unsigned.

Note: free() should be on the same level than malloc()
Memory allocation

malloc/calloc can always return NULL.

- Must check.
- Happens too late.
- Hard to test (ulimit)
- Hard to recover
- Replace by cover functions
- With possible guards
- Performance variation
- Memory pool for many identical small calls
- Use memset/memcpy (string.h)
- memory leaks/overruns
- use after free (linked list)
#include <stdio.h>
#include <stdlib.h>

int main() {
    int count = 0;

    while(NULL != malloc(1024*1024*1024)) {
        count++;
        printf("Got %4d GB\n", count);
    }
    printf("Out of memory after %d GB\n", count);
}
$ ./a.out

Got    1 GB
Got    2 GB
Got    3 GB
Got    4 GB
Got    5 GB

...

Got 114423 GB
Got 114424 GB
Got 114425 GB
Got 114426 GB
Got 114427 GB

Out of memory after 114427 GB
#include <stdio.h>
#include <stdlib.h>

int main()
{
    int count = 0;
    int* p;

    while(NULL != (p = malloc(1024*1024*1024)))
    {
        for(int i = 0; i < 1024*1024; i++)
            p[i * 1024 / sizeof(*p)] = 5;

        count++;
        printf("Got %4d GB\n", count);
    }

    printf("Out of memory after %d GB\n", count);
}
$ ./a.out

    printf("d=%lu\n", offsetof(struct cxid, d));
}

c=0
x=1
i=4
d=8
```c
#include <stdio.h>
#include <stddef.h>

typedef union { char c; int i; double d; short s[4]; } CIDS;

static CIDS cids = { .d = 12.4 }; 

int main()
{
    printf("size cids=%lu\n", sizeof(cids)); 
    printf("offset d=%lu\n", offsetof(CIDS, d));
    printf("d=%f\n", cids.d);
    printf("c=%d\n", cids.c);
    printf("i=%d\n", cids.i);

    size cids=8
    offset d=0
    d=12.400000
    c=51
    i=858993459
}
```
Exercise 4

Write a program in C, which enumerates all solutions to a binary program of the form:

$$Ax \leq b, \ x \in \{0,1\}$$

with $A$ being a $m \times n$ matrix, and $b$ a $m$ vector, with $m,n \leq 32$.

Example:

$$2 \ x_1 + 3 \ x_2 + 5 \ x_3 - 4 \ x_4 \leq 8$$
$$3 \ x_{1-1} - 6 \ x_2 + 8 \ x_4 \leq 10$$
$$x_3 + x_4 \leq 1$$
Exercise 4

The input format for the above would be:

4  # columns (variables)
3  # rows (constraints)
2 3 5 4 <= 8
3 6 0 8 <= 10
0 0 1 1 <= 1

Everything after an # in a line should be discarded as a comment.

The program should read the data from a file and write out all solution vectors.
Overall Program Design

- Data flow
- Control flow
- Hierarchical dependencies
